Project Objective

Team ID	PNT2022TMID33385
Project Name	Intelligent vehicle damage assessment & cost estimator for insurance companies.

Objective

Use computer vision and deep learning techniques to accurately classify vehicle damage tofacilitate claims triage by training convolution neural networks.

Use Case

The rapidly expanding automobile industry highly backs the equally fast-growing auto insurance market. Although until now this industry has been solely based on traditional ways to make repair claims. In case of an unfortunate accident, the claims for the car damage needsto be filed manually. An inspector is required to physically analyse the vehicles to assess the damage and obtain a cost estimate. In such situation, there is also the possibility of inaccuratesettlements due to human errors. Automating such a process with the help of machine learning and remote usage would make the process a lot more convenient for both sides of thedamage, increasing productivity of the insurance carrier and satisfaction of the customer.

While the technology is yet to achieve the highest possible levels of accuracy, above is a proof of concept of the application of Deep Learning and Computer Vision into automatingthe damage assessments by building and training Convolution Neural Networks.

Solution

To automate such a system, the easiest method would be to build a Convolution Neural Network model capable of accepting images from the user and determining the location andseverity of the damage. The model is required to pass through multiple checks that would first ensure that given image is that of a car and then to ensure that it is in fact damaged.
These are the gate checks before the analysis begins. Once all the gate checks have been validated, the damage check will commence. The model will predict the location of the damage as in front, side or rear, and the severity of such a damage as in minor, moderate orsevere.

The model accepts an input image from the user and processes it across 4 stages:

1. Validates that given image is of a car.

2. Validates that the car is damaged.

3. Finds location of damage as front, rear, or side

4. Determines severity of damage as minor, moderate, or

severe

The model can also further be improved to:

1. Obtain a cost estimate

2. Send assessment to insurance carrier

3. Print documentation

Challenges:

1. The field of Computer Vision is yet developing and not mature enough to deal with modular phone camera quality images. Angle, lighting, resolution are factors that caneasily cause major disruptions in image classification.

2. Car insurance settlement claims require near perfect accuracy to ensure the customeris not frauded in the process. Such models would be required to be trained on humongous datasets which are highly difficult to procure.

3. To run such heavy datasets to ensure maximum accuracy would be imposed by hardware restriction. Storing, training, and deploying such heavy datasets over thecloud would require expensive architecture.

4. While the computer can avoid human errors, there are often situation that wouldrequire such a model to flag for human assistance.

5. Systems running on the Cloud, especially those dealing monetary data are also heavily susceptible to cyber risks and require heavily structured frameworks to ensurecustomer data security.

6. Such a process will require a certain level of manual control and filter to avoidflooding of fraudulent insurance claims.

Model Architecture and Pipeline

Our system architecture is built around the following modules:

1. User Input: User submits image containing the damage.

2. Gate 1: Checks to ensure the submitted image contains a car.

3. Gate 2: Checks to ensure the submitted image of car is damaged avoiding fraudulentclaims.

4. Location Assessment: Tests image against the pre-trained model to locate damage

5. Severity Assessment: Tests image against pre-trained models to determine

theseverity of damage.

6. Results: The results are sent back to the user and third party.

Tools and Frameworks Used

Data Set Collection:

1. Google Images – data source

2. Stanford Car Image Dataset – data source

3. Import.io – online web data scraper

Model Development:

1. TensorFlow – Deep Learning Library

2. Keras – Deep Learning Library

3. NumPy – Scientific numerical calculations library

4. Scikit-learn – Machine learning algorithms

tools**Web Development:**

1. Flask – Python web framework

2. Bootstrap – HTML, CSS, JavaScript

framework**Development Environment:**

1. PyCharm IDE – Python program development environment

2. Jupyter Notebooks – web application for interactive data science and scientificcomputing

3. Anaconda Virtual Environments – python virtual environment

application**Libraries Used:**

1. numpy

2. pandas

3. matplotlib

4. sklearn

5. seaborn

6. pickle

7. IPython

8. collections

9. h5py

10. json

11. Urllib

Improving The Model:

1. The data set used in this application consisted of around 1500 images for the first gatecheck, while the classification models were trained on only 400 images per class, while the validation dataset had approximately 75 to 100 images each class. Such amodel will have low accuracy.

2. With a wider range of data set featuring multiple components of the car, the modelcan also be trained to identify what components are damaged, also classifying the varying degree of damage of each.

3. With a highly expansive dataset containing the make, model, year of the car and the possible cost estimates for the varying degrees of damage, the model can also predictthe value for the user, before he submits the more advanced and detailed assessment for evaluation.

4. Using more secure and durable hardware, the entire system can be built on the Cloudto run remotely and from the user's cellular device itself.

5. The application can also be updated to recommend the user of policies pertaining tothe specific accounts and other insurance benefits.
